

# What is the difference between the repository pattern and the client-server pattern ?

## client-server patterns

Client server pattern is a network architecture that consist of a server and multiple clients. Servers are powerful and it will provide service to .multiple client components  
Used when data in a shared database has to be accessed from a range of locations

## The Repository pattern

The Repository pattern is an abstraction over persistent storage. It hides the boring details of data access by pretending that all of our data is in memory.  
We use this pattern when you have a system in which large information is stored for a long time
